## Overview

This Tutorial simulates the starting of a car engine when the petrol tank is 75% full using one Kookaberry. You will then connect it to another Kookaberry and show how the engine can only be started when the tank is both 75% full AND an ignition button is pressed.

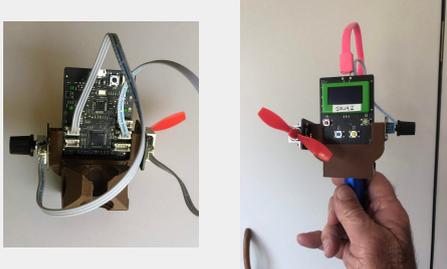

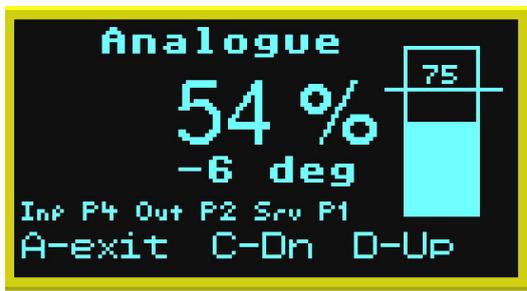

This simple and fun example illustrates how using the Kookaberry in your lesson plans supports many DT content descriptions and outcomes including

- ST3-11DI-T: Explains how digital systems represent data, connect together to form networks and transmit data
- [ACTDIK014](#) : Examine the main components of common digital systems and how they may connect together to form networks to transmit data
- [ACTDIP016](#): Acquire, store and validate different types of data, and use a range of software to interpret and visualise data to create information.

You will be using the [Analogue](#) and [Logic](#) apps. The Analogue app displays a varying level of voltage from an analogue input and triggers a control signal at an adjustable threshold.

The Logic app illustrates the operation of the various Boolean algebra logic gates used to perform mathematical calculations in a computer. We will be using the AND and OR gates (the first two) for this tutorial.

## Introducing the motor and the petrol tank

Step	Description	Resource
1	Attach a <a href="#">fan module</a> to one side of a Kookaberry handle using the small screws in your kit, and a <a href="#">potentiometer</a> to the other. Connect the fan to P2 and the potentiometer to P4	
2	Run the Analogue app and set the threshold to 75% using the C and D buttons. Rotating the potentiometer progressively alters the input voltage at connector P4. When the voltage input is in excess of 75% of its total range (between 0 and 3v), an output signal of 3v is sent to connector P2 .

Step	Description
3	<p>Turning the potentiometer to vary the voltage applied to P4 simulates filling a petrol tank at a pump; and the 75% threshold the level at which the driver determines when the car is OK to start. This is demonstrated by the fan motor operating automatically when the threshold is reached.</p> <p>However, we don't want the car to start automatically once the petrol tank reaches a certain level – we want control over when it starts. This is where the next stage of this Tutorial kicks in.</p> <p>But first an explanation of the Logic app which we will use to add an ignition switch.</p>

## Logic App Basics

The Logic app provides a physical representation of the five Boolean states – AND, OR, NAND, NOR, and XOR. These are commonly referred to as Gates and are fundamental computer mathematical elements. Two inputs (P4 and P5) are showing leading into a gate which, depending upon the logic state and the combination of inputs, will produce an output on P2.

*It sounds more complicated than it really is. Far easier to just try out the various modes. This is where the Kookaberry really helps by bringing theory to life.*

The Gate logic is as follows. We will use the AND Gate in this Tutorial.

1. **AND Gate:** If both P4 **AND** P5 are ON = P2 is ON. If one input is ON and the other OFF, P2 is OFF
2. **OR Gate:** If either P4 **OR** P5 are ON= P2 is ON. **ALSO** if both inputs are ON, then P2 is also ON (See also XOR gate). If both inputs are OFF, P2 is OFF
3. **NAND (Not AND) Gate:** If both P4 **AND** P5 are OFF = P2 is ON. If one input is OFF and other ON, P2 is ON
4. **NOR Gate (Not OR):** If either P4 **OR** P5 is OFF= P2 is ON. If either, or both, inputs are ON, P2 is OFF
5. **XOR (Exclusive OR):** This is the same as the OR Gate except that if both inputs are ON, P2 remains OFF.

Inputs P4 and P5 can be turned ON by pressing Buttons C or D respectively .

### *What is happening within the Kookaberry?*

The Logic programme continuously checks for the presence or absence (also known as the “state”) of an input signal at P4 and P5. If it detects 3 volts, it determines that the connection is in an ON state and shows a “1” against the appropriate connector on the screen. If there is no signal, it assumes the connection is OFF and shows a “0”.

The introduction of logic gates in primary school years may appear premature, but they are interesting and have been shown to be easily understood when presented in this practical context.
